### **CLEAN CODE ARCHITECTURE USING RIVERPOD PROVIDER**

Unidirectional data flow from the data layer

Simplified architecture when fetching data.

# The process to fetch the API Data using riverpod in the clean code architecture

- 1. The widget watches a **FutureProvider**, which in turn calls a repository method that will retrieve the data
- 2. The repository fetches the data from the data source
- Once a response is received, it is parsed and returned from the repository (and the attached **FutureProvider**, which also caches the data)
- The widget receives the data as an AsyncValue<Model> and maps it to the UI

# **Layers in Clean Code Architecture**

**Presentation layer** is responsible for handling user interface logic.

- Includes widgets, providers, and UI components.
- Should be kept as thin as possible, delegating business logic to other layers.

**Domain layer** contains the business logic and rules of the application.

- Independent of any UI framework or external dependencies.
- Creating the data models using the Freezed plugins for JSON serialisation.
- · Defines entities and repositories.

**Data layer** handles data access and storage.

- Includes databases, API calls, and local storage.
- Repositories are implemented here to fetch and store data.
- Created the riverpod providers to interacting with the data models

# **Products Application**

Products List Screen.

Product Detail Screen

Error Screen (if internet connection gets lost)
